CMSE381_F2025_Schedule : Schedule

Lec #	Date		Topic	Reading	HW
1	M	8/25	Intro / Python Review	1	
2	W	8/27	What is statistical learning	2.1	
3	F	8.29	Assessing Model Accuracy	2.2.1, 2.2.2	
	M	9/1	Labor Day - No Class		
4	W	9/3	Linear Regression	3.1	
5	F	9/5	More Linear Regression	3.1	HW #1 Due Sun 9/7
6	M	9/8	Multi-linear Regression	3.2	
7	W	9/10	Probably More Linear Regression	3.3	
8	F	9/12	Last of the Linear Regression		HW #2 Due Sun 9/14
9	M	9/15	Intro to classification, Bayes classifier, KNN classifier	2.2.3	
10	W	9/17	Logistic Regression	4.1, 4.2, 4.3.1-3	
11	F	9/19	Multiple Logistic Regression / Multinomial Logistic Regression	4.3.4-5	HW #3 Due Sun 9/21
	M	9/22	***Project Day & Review***		
	W	9/24	**Midterm #1**		
12	F	9/26	Leave one out CV	5.1.1, 5.1.2	

Last Time:

- Finished Linear Regression

Announcements:

- Homework #3 Due Sunday Sep 21
- Next Monday - Review day
  - Nothing prepped
  - Bring your questions
  - Send your questions (survey)
- Wed 9/24 - Exam #1
  - Bring 8.5x11 sheet of paper
  - Handwritten both sides
  - Anything you want on it, but must be your work
  - You will turn it in

Covered in this lecture

- Ch 2.2.3
- Error rate (classification)
- Bayes Classifier
- K-NN classification

Section 1

Classification Overview

What is classification

Classification: When the response variable is qualitative

- qualitative: Unordered set
- Examples
  - Eye color $\in \{brown, blue, green\}$
  - $email \in \{spam, notspam\}$

- Given feature vector X and qualitative response Y in the set S, the goal is to find a function (classifier) $C(X)$ taking X as input and predicting its value for Y.
- We are more interested in estimating the probabilities that X belongs to each category

Some examples

Discuss what set Y comes from in each case

- Predict whether a COVID19 vaccine will work on a patient given patient's age
- An online banking service wants to determine whether a transaction being performed is fraudulent on the basis of the user's IP address, past transactions, etc.

Section 2

Ch 2.2.3: Classification

Error rate

- Training data:
  $\{(x_1, y_1), \cdots, (x_n, y_n)\}$ with y_i qualitative
- Estimate $\hat{y} = \hat{f}(x)$
- Indicator variable
  $\mathrm{I}(y_i \neq \hat{y}_i)$ *is 1 if not the same (misclassified) and 0 else*

Training error rate:

$$\frac{1}{n}\sum_{i=1}^{n} \mathrm{I}(y_i \neq \hat{y}_i)$$

Test error rate:

$$\mathrm{Ave}(\mathrm{I}(y_0 \neq \hat{y}_0))$$

Good classifier: one that minimizes test error rate

Best ever classifier

We can't have nice things

Bayes Classifier:
Give every observation the highest probability class given its predictor variables

$$\Pr(Y = j \mid X = x_0)$$

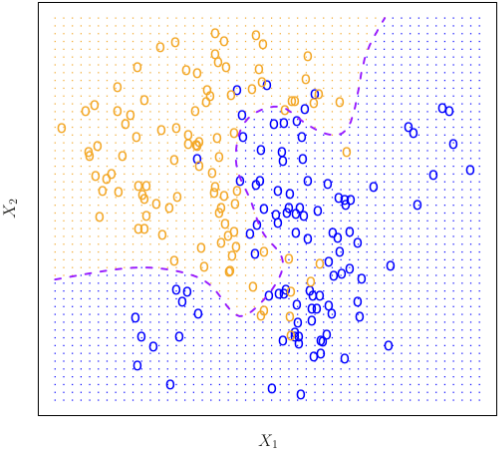
- It is possible to show (though the proof is outside of the scope of this book) that the test error rate is minimized, on average, by a very simple classifier that assigns each observation to the most likely class, given its predictor values.

An example

- Survey students for amount of programming experience, and current GPA
- Try to predict if they will pass CMSE 381.
- If we have a survey of all students that could ever exist, we can determine the probability of failure given combo of those features.

- No single classifier will get it right 100% since students with the same features might pass or fail

Bayes decision boundary



- Example where we simulated the data, so we know the conditional probability of each value of X_1 and X_2, using Bayes Theorem:

$$P(Blue|X_1, X_2) = \frac{P(X_1, X_2|Blue)P(Blue)}{P(X_1, X_2)}$$

$$Posterior = \frac{likelihood \cdot prior}{marginal}$$

- The purple line is where we switch our predictor, called the Bayes decision boundary

Bayes error rate

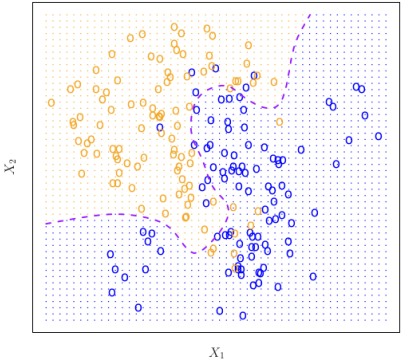
- Error at $X = x_0$ *The j with the highest value is what's predicted by Bayes for that x_0, so this is probability that the Bayes classifier is wrong*

$$1 - \max_j \Pr(Y = j \mid X = x_0)$$

- Overall Bayes error: *This is expectation over all x_0. This is the analagous to irreduceable error*

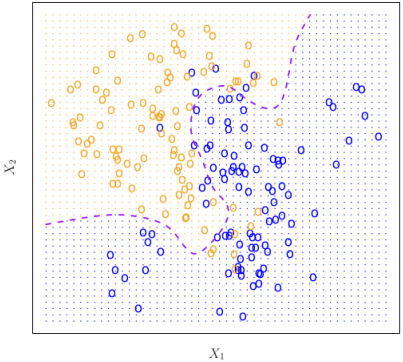
$$1 - E\left(\max_j \Pr(Y = j \mid X = x_0)\right)$$

This is the irreduceable error



The game

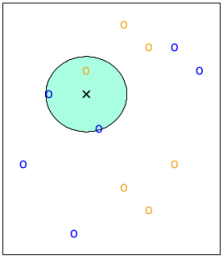
- Challenge: typically don't know the ground truth likelihood
- Game: do as good a job as possible estimating the Bayes decision boundary, by guessing the posterior $P(Blue|X_1, X_2)$ and $P(Yellow|X_1, X_2)$
- Classify given observation with highest estimated probability



Section 3

K-Nearest Neighbors Classifier

K-Nearest Neighbors

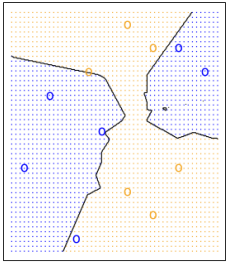


$K = 3$

- Fix K positive integer
- $N(x)$ = the set of K closest neighbors to x
- Estimate conditional proability

$$\Pr(Y = j \mid X = x_0) = \frac{1}{K} \sum_{i \in N(x_0)} \mathrm{I}(y_i = j)$$

- Pick j with highest value

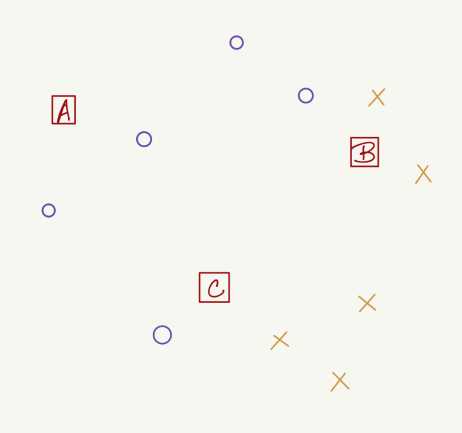


Black line: KNN decision boundary

Note this is not Bayes like in 2 slides! stupid textbook

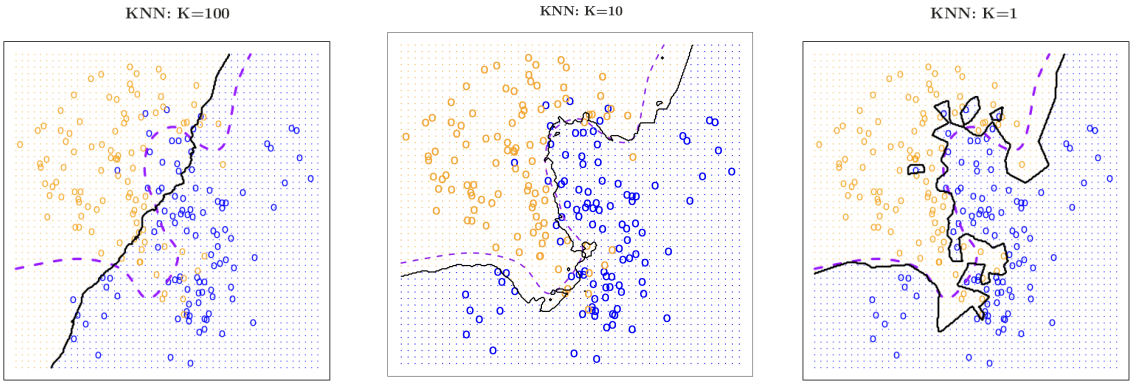
Example

Here label is shown by O vs X. What are the knn predictions for points A, B and C for $k = 1$ or $k = 3$? *Next year, maybe make an example like this with more than two levels, and/or try to decide what locations get which predictions for k=1 in prep for the next slide*



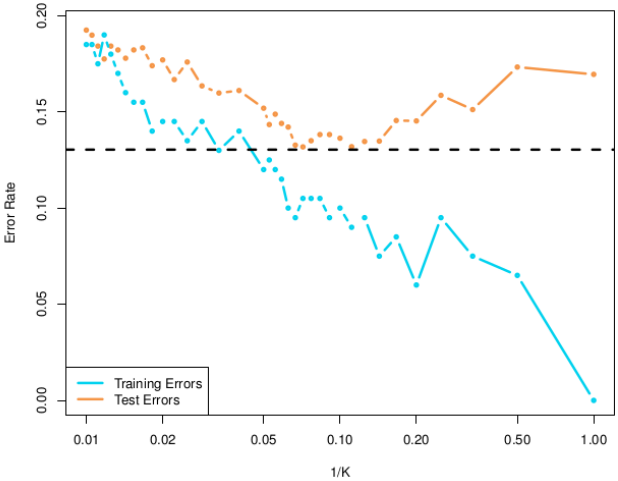
Point	$k = 1$ Prediction	$k = 3$ Prediction
A	*O*	*O*
B	*X*	*X*
C	*O*	*X*

Tradeoff



- Purple is Bayes decision boundary. Same on both
- $K = 1$, boundary is overly flexible, finds patterns not there
- $K = 100$ not enough flexibility

More on tradeoff



- right side, $K = 1$, training is 0 error but high test error
- Test error has same U shape as bias-variance tradeoff in regression setting: decline at first, then increase again when overfitting
